Language-Conditioned QAOA for Portfolio Selection: A Bias-Controlled Study Reveals a Training-Horizon Confound

Abstract. We introduce *language-conditioned* QAOA: a pipeline in which a large language model (LLM) reads financial news and emits per-asset convictions that tilt the cost Hamiltonian of a cardinality-constrained Quantum Approximate Optimization Algorithm (QAOA) portfolio optimizer. We then ask, with strong bias controls, whether the language adds out-of-sample value. It appears to: an LLM released during the evaluation window (qwen2.5-14B, Sept. 2024) beats matched random tilts by $+0.76\%$/quarter ($p \approx 0$). But a *genuinely out-of-sample* LLM (Llama 2, cutoff Sept. 2022) on the *same* headlines yields -0.23% ($p = 0.94$, indistinguishable from random): the benefit appears only for the model released into the test period—consistent with *training-horizon hindsight* rather than prediction (the pre-cutoff model is also smaller, a caveat we note). We contribute the language→quantum conditioning pipeline, a reusable bias-control template, and a quantified training-horizon look-ahead warning for LLM-for-finance evaluation.

1 Pipeline and Method

Two lines straddle a gap: Lee et al. [4] drive Black–Litterman views with an LLM but optimize *classically*, while Chen et al. [2] bring numerically predicted views into a *quantum* pipeline with no natural language. We occupy the middle—an LLM's language conditions the quantum optimizer—and treat "do news views help?" as a *measurement problem*. Holding B of n assets to maximize the mean–variance objective $\mu^\top x - q\, x^\top \Sigma x$ over a fixed Dow-30 universe (current, not point-in-time, constituents; CRSP returns; shrinkage covariance), we map this binary selection to a diagonal Ising Hamiltonian solved by QAOA [3]. A local LLM reads RavenPack news headlines time-stamped *strictly before* each quarterly decision date into convictions $v_i \in [-1, 1]$; a $\pm 10\%$ view tilts $\mu \to \mu + s\, v$ (the standard sentiment-to-view convention), estimated on the train window and evaluated on the held-out next quarter. Bias controls: hundreds of (subset × window) instances from a fixed seed, pre-registered metrics, a matched-random-tilt *placebo*, an off-the-shelf-sentiment (RavenPack ESS) ablation, and—decisively—two LLMs on the *same* headlines: **qwen2.5-14B** (released Sept. 2024, training

plausibly *spans* the window) and **Llama 2** (documented cutoff Sept. 2022, *before* it). The language effect is read at the exact optimum, free of optimizer noise.

2 Results

Over 1,600 instances (Dow 30, n=14 qubits, hold 5, four quarterly dates 2023-12–2024-09), the training-overlapping LLM beats matched random tilts by a language-specific premium of $+0.76\%$/quarter on changed-optimum instances (instance-level $p \approx 0$, positive in $3/4$ quarters); the pre-cutoff LLM, on identical headlines, yields -0.23% ($p = 0.94$, $2/4$)—indistinguishable from random (Fig. 1). The conditioning has real mechanism leverage (a $\pm 10\%$ view changes the exact optimum in 47–68% of instances), yet QAOA at depth p=4 recovers the true optimum only 7.7% of the time; we make no quantum-advantage claim. Limitations: four decision dates (instance-level p is pseudo-replicated); the clean and contaminated LLMs differ in capability as well as cutoff, so the two are not fully separated; small-n simulation; fixed-membership large-cap US; no costs. None overturn the takeaway: an LLM whose training overlaps the backtest can manufacture out-of-sample "alpha" that a pre-cutoff model does not—a look-ahead that LLM-for-finance studies must guard against by dating their model against the evaluation window. Fixed seeds; code released upon publication.

Acknowledgments. This manuscript's prose and figure-generation code were drafted with help from a large language model [1]; the questions, methods, results, and claims are the authors' own and were verified by them.
